ABSTRACT

In this context, an Arduino-based alcohol detector is an example of a device that has the potential to detect the presence of alcohol in the surrounding environment. It is possible to use this tool to check the results of individuals who have drunk alcohol while operating a motor vehicle. A MQ-3 alcohol sensor is utilized by the device in order to ascertain whether or not alcohol is readily available. The component that constitutes the sensor is the component that heats the layer of conducting material while simultaneously measuring the resistance of the substrate. There is a change in the resistance of the MQ-3 sensor whenever it is subjected to scents or vapors of alcohol. Signals of both digital and analogue types can be obtained from the sensor. A distinction can be made between the two in a very plain way. There are only two conceivable states that digital output can take while communicating with a microcontroller. These states are high and low, which means that they represent the values 1 and 0, respectively. An analog signal, on the other hand, is received by the microcontroller, and it provides an indication of the amount of alcohol present in the environment by utilizing a wide range of values, ranging from 0 to 1023. An LED, a MQ-3 alcohol sensor, and an Arduino Uno are two of the components that are required to construct the device. In confined areas or for showing straightforward applications on a small scale, this device performs admirably. The process of installing the gadget in vehicles is yet another approach that may be used to lessen the number of accidents that are caused by drunk driving. In addition to being user-friendly and easy to repair, the device has a high level of sensitivity to alcohol.

Keywords: Arduino-based alcohol detector; MQ-3 alcohol sensor; Microcontroller; Sensitivity; Alcohol.

1. Introduction

An alcohol detector is a piece of equipment that has the capability of determining whether or not alcohol is present in the bloodstream or in the breath. It is often used to reduce the number of accidents that are caused by drunk driving and other mishaps related to alcohol. An effective method for constructing an alcohol detector is to make use of an Arduino microcontroller in conjunction with a MQ-3 alcohol sensor. The MQ-3 sensor is an example of a portable, low-cost gadget that is capable of detecting ethanol in the air [1]. Heating a layer of conductive material and continuously monitoring its resistance is the method that is utilized in this procedure. The resistance of the MQ-3 sensor is altered when scents or vapours containing alcohol are inhaled. Signals of both digital and analogue types can be obtained from the sensor. It is possible to successfully connect the MQ-3 sensor to the Arduino board in a short amount of time and with only a few jumper wires. The sensor is capable of providing both digital and analog readings of the data [2]. Digital output, on the other hand, can only send binary values of 1 or 0 to the microcontroller [3]. This is in contrast to analog outputs, which may send a greater range of values to the microcontroller, ranging from 0 to 1023. This range corresponds to the amount of alcohol that is present in the atmosphere around the microcontroller.

A board for microcontrollers known as the Arduino Uno is built on top of the ATmega328P, which acts as its foundation. A USB port, a power connector, a reset button, a quartz crystal operating at 16MHz, six analog inputs, and fourteen digital input/output pins are just some of the numerous features that it possesses. The presence of alcohol can be determined by attaching a MQ-3 alcohol sensor to an Arduino Uno. This allows for the detection of alcohol. The MQ-3 sensor is able to detect gasses because it is able to identify chemical reactions [4]. The
 temperature of a metal oxide semiconductor (MOS) sensor is brought up to the desired level by a tiny heating element that is incorporated inside the sensor. Because of its adaptability, Arduino is utilized in a wide variety of circuits and applications. Additionally, it can be utilized as a portable breathalyzer for the detection of alcohol, as well as an alarm for gas levels that are excessively high. In addition to this, it has the capability of being incorporated into environmental monitoring systems or utilized as a sensor module that operates independently. In addition, other technological sectors, like as alcohol detection systems for vehicles, are evidence of the versatility and significance of Arduino [5].

A reduction in the number of accidents that are brought on by drunk driving is the primary objective of the construction of an alcohol detector that is based on Arduino. Getting behind the wheel after having consumed alcohol is a serious offense that can result in accidents that are quite destructive. This gadget can be used to determine whether or not a person has consumed alcohol prior to driving, as well as to ensure that these individuals do not drink and drive [6]. Electronic components like as LEDs, an Arduino board, and a MQ-3 alcohol sensor are required in order to construct the device. Through the utilization of the MQ-3 sensor, one can easily and inexpensively determine whether or not there is alcohol present in the atmosphere. Signals of both digital and analogue types could be produced by the sensor. An alcohol detection system that is based on Arduino has the primary purpose of identifying the presence of alcohol in the breath that is exhaled by a person and then notifying the user of this discovery [7]. The adoption of this technology has the potential to lessen the number of accidents that are brought on by alcohol, including those that include drunk driving. A MQ-3 alcohol sensor is utilized by the device in order to ascertain whether or not alcohol is present in the atmosphere. A board made of Arduino is utilized in order to link the sensor and do data analysis. The activation of an alert will occur if the concentration of alcohol is greater than a predetermined threshold [8].

The incorporation of an alcohol detection system that is based on Arduino will assist in accomplishing a greater number of important goals. Developing an alcohol detection gadget is the primary objective, and the Arduino technology, which is based on a breath analyzer, will be used to accomplish this. By providing assistance to law enforcement in the process of quickly identifying and apprehending drunk drivers, the purpose of this technology is to improve the safety of the roads. Also, we want to make sure that our alcohol detector is dependable and functions properly so that we can reduce the number of accidents that are caused by drivers who are under the influence of alcohol. To facilitate speedy decision-making, the system is designed to provide accurate alcohol level assessments in a timely manner [9]. In addition, the objective is to develop a device that is simple to operate, requires little training, can be finished in a predetermined amount of time, and takes into account the user's financial constraints. In conclusion, in order to guarantee the achievement of high-quality results, the performance of the system will be evaluated in accordance with the requirements established by ISO/IEC 9126. The functionality, dependability, usability, efficiency, maintainability, and portability of the system will all be evaluated through the applications of these standards.

An alcohol sensor is one method that can be utilized to analyze the quantity of alcohol gas present in the atmosphere. The voltage that it produces as an output is an analog voltage. As long as the 5V power source is less than 150 mA, the sensor can be operated in temperatures ranging from -10 to 50 degrees Celsius. Its sensitivity
range, which goes from 0.04 mg/L to 4 mg/L, makes this device an excellent choice for use in breathalyzers because of its wide range of sensitivity [10]. An alcohol detector that makes use of an Arduino board is one method that can be utilized to ascertain whether or not there is alcohol present in the atmosphere [11]. There is a high probability that the device will be equipped with an Arduino board, an LED, and a MQ-3 alcohol sensor. Utilizing semiconductor technology, the MQ-3 alcohol sensor is able to determine the amount of alcohol present in the atmosphere. Signals of both digital and analogue types could be produced by the sensor.

2. Literature Survey

Drunk driving is currently the most common reason for accidents that occur on the road. Drivers who are under the influence of alcohol are unstable, which increases the risk that they may drive recklessly on expressways, putting not only themselves but also other drivers and pedestrians in danger [12]. Driving under the influence of alcohol and doing so at the same time is a serious offense that carries a lot of consequences. This topic, which now poses a significant threat to the general population's health, has the potential to become substantially more troublesome in the near future. The planned arrangement is intended to reduce the number of accidents that occur as a result of drunk driving in the future and to make driving safer in general. The research of this topic makes extensive use of electronic sensors and microcontrollers in a variety of different circumstances [13]. The creation of an alcohol sensor that is able to detect oscillations in the amount of alcohol particles in the atmosphere is the primary objective of this group of researchers. A breathalyzer is the name given to this type of detector since it is able to determine the amount of alcohol that is present in the breath of a person. This product's detector, microprocessor, and other electrical components quickly cut gasoline to the engine upon detecting the presence of alcohol, thereby putting a halt to the running of the engine [14]. This measure is taken to ensure the safety of passengers by preventing drivers who are under the influence of alcohol from continuing to operate their vehicles during the time that they are under the influence of alcohol.

In nations that have reached a level of civilization, drinking alcohol is regarded as socially acceptable. The practice of following customs that are observed during celebrations and a variety of private events is also connected to this activity [15]. People's behavior is altered when they consume even a tiny amount of alcohol since it causes them to become less active and more sedentary at the same time. The consumption of alcohol alters the amount of alcohol that is present in a person's blood, which in turn has an effect on the physiological processes that occur in that individual [16]. There is a direct connection between blood alcohol concentration and the concentration of alcohol in the breath. In a circumstance like this, the inability to exercise control over one's own behavior is particularly hazardous because it might result in automobile collisions, which in turn put the lives of everyone else on the road in potential danger [17]. When it comes to addressing criminal actions, the legal system has a wide variety of weapons at its disposal, two of which are the administration of fines and the suspension of licenses. All of these symptoms indicate to the necessity of a straightforward and precise treatment. The authors describe in full the process of developing and putting into operation a system that automatically turns off the engine of a car when it detects that the amount of alcohol in the vehicle is excessively high. Within the context of this configuration, an Arduino UNO and an ultrasonic sensor collaborate. The data from the alcohol detection sensor will be monitored at all times by the system, and if they are found to be higher than a certain threshold, the system will immediately
disengage the power supply to the car. In an effort to lessen the number of accidents that are caused by drunk driving and to minimize the number of accidents that are caused by drunk driving, the author developed a method for preventing car accidents that incorporates an alcohol detector [18].

In this study, the authors offer an alcohol sensor device and system, which is widely recognized as one of the most effective methods for determining the blood alcohol concentration (BAC) of humans. Another piece of equipment has the capability to determine the amount of alcohol that the driver has ingested and notify the appropriate authorities if the driver's blood alcohol content (BAC) is higher than a predetermined threshold. After detecting the presence of alcohol, the gadget will immediately reduce the speed of the DC motor as a precautionary measure [19].

According to the findings of a recent study, a device that can identify whether a driver is puffing on their breath and disables the vehicle if the blood alcohol concentration is sufficiently high has been developed. These examples are representative of a limited number of literature reviews that focus on devices that detect alcohol. In order to determine the amount of alcohol that is present in the air that someone breathes in, an alcohol detection device that is based on Arduino is a straightforward and cost-effective method. Within the framework of the system is a well-known and exceptionally precise alcohol vapor detector known as the MQ-3 [20]. When the sensor detects the presence of alcohol vapors, it will flash both its status LED and its power LED, both of which are built into the gadget itself. Signals of both digital and analogue types could be produced by the sensor. All the way from 0 to 1023 is the extensive range of values that are communicated by the analog signal, which is correlated to the alcohol concentration in the surrounding environment [21].

A few straightforward components, such as an Arduino Uno board, a MQ-3 alcohol sensor, and a red LED, are all that are required to construct the system if you choose to do so. A conducting layer is heated with a heating element in order to provide the MQ-3 sensor with the ability to monitor the resistance of the layer in real time. The resistance of the MQ-3 sensor is altered when scents or vapours containing alcohol are inhaled. You have the ability to modify the level of amplification using the potentiometers that are included with the sensor.

3. Proposed System

It is possible to build an alcohol detector by utilizing an Arduino and a MQ-3 alcohol sensor both together. It is the MQ-3 metal oxide semiconductor (MOS) sensor that is responsible for adjusting its electrical resistance in response to the amount of alcohol that is present in the air. Signals of both digital and analogue types could be produced by the sensor. A microcontroller receives only binary values (1 or 0) from digital output, whereas an analog signal offers a wide range of values (0 to 1023) that reflect the various amounts of alcohol in the environment. This is the primary distinction between digital output and analog signal. Digital output only transmits binary values to a microcontroller. Arduino, along with a variety of other components, can be utilized in the construction of an alcohol detector. The Arduino Uno is the ideal option for beginners because of how simple it is to use and how many resources are available to them. They include every type of microcontroller, but the Arduino Uno is the best option. Moreover, a MQ-3 alcohol sensor is necessary in order to provide accurate detection of the level of alcohol present. In addition, a red light-emitting diode (LED) that serves as a visual signal will light up if the sensor detects the presence of alcohol. The first step in constructing an alcohol detector using Arduino is to put all of these
components together for assembly. This simple project may be finished by using only fundamental components like as an Arduino, an LED, and alcohol sensors that are readily available. Additionally incorporated into the sensor are a power LED as well as a status LED. An intermittent blinking of the status LED will occur whenever the sensor detects the presence of alcohol vapors.

3.1. Flowchart

In order for the MQ-3 sensor to detect gasses, it must first undergo a chemical reaction. The MOS sensor goes through a chemical reaction that causes it to change its electrical resistance when it is exposed to the fumes of alcohol that are present in the atmosphere. After then, the sensor will transmit a signal to a microcontroller, which can then be utilized to initiate a process or an alarm, depending on the situation.
3.2. Working Principle

Vapours of alcohol can be detected by the MQ-3 sensor at concentrations ranging from 0.1 mg/L to 10 mg/L. Because of the non-linear relationship that exists between fluctuations in concentration and voltage, a lookup table is required in order to obtain reliable readings across the extensive range of alcohol concentrations at which alcohol can be found. Due to the fact that it is able to detect even minute levels of alcohol in the air, it is an excellent component for breathalyzers.

3.3. Arduino Uno with MQ-3 Sensor

By calibrating the sensor in a controlled environment with a known amount of alcohol concentration, it is possible to avoid producing findings that are misleading. In the case that the data determined by the sensor are inaccurate, this process will be of assistance in recovering them. Due to the fact that it is inexpensive and simple to operate, the MQ-3 sensor has gained popularity among amateurs and people who undertake their own DIY projects.

3.4. Alcohol Detection System

One of the most well-known applications of Arduino is in the detection of alcohol, with the MQ-3 alcohol sensor being a component that is frequently used. There are a wide variety of applications for this sensor, including the detection of gas levels that exceed specified limits, the detection of alcohol as a portable device, the function of a breathalyzer, the function of a sensing module on its own, and the inclusion of this sensor in environmental monitoring equipment and alcohol detectors for automobiles. The amount of alcohol that is present in the air may be determined by this sensor, which can provide you with data in both digital and analogue formats. An integrated amplifier found in the LM393 integrated circuit makes it possible to detect the voltage signal, and the MQ-3 sensor
is equipped with this capability. It is possible to adjust the levels of amplification by using the potentiometers that are included in the sensor. Because of its extraordinary sensitivity to ethanol and alcohol, the sensor is particularly user-friendly and simple to use.

3.5. Circuit Diagram of the Proposed Design

3.5.1. Circuit Diagram
3.5.2. Block Diagram

(a) Arduino UNO

The Arduino Uno is an example of an open-source microcontroller board that makes use of the ATmega328P microprocessor from Microchip. It was constructed by Arduino, and it operates on the Harvard architecture, which means that the data and the code are stored in various locations within the memory. Data memory and program memory are the two types of memory that are utilized in this architecture. Program memory is responsible for storing the code located in flash memory. The most important characteristics of the device are as follows: An ATmega328P is the type of microcontroller that is being used, and its clock speed is 16 MHz. 32 KB of flash memory, 2 KB of SRAM, and 1 KB of EEPROM are all included in its system. Some 0.5 KB of these are utilized by the bootloader. Due to the fact that it is so simple to use and has such a wide range of applications, the Arduino Uno is a board that is favored by all users, from novices to seasoned professionals. This is due to the fact that it is rather versatile and has an interface that is easy to use, both of which make it suitable for a wide range of projects and jobs. As a result of its user-friendly design, which stimulates both experimentation and learning, this product has become an indispensable instrument in the maker community as well as in other sectors. With the Arduino Uno, users are able to bring their inventive concepts to life by utilizing a large selection of compatible sensors, actuators, and shields. This is true regardless of whether they are working on a simple LED project or constructing complicated robotic systems and applications for the Internet of Things. As a result of the platform's active community, which encourages collaboration and the exchange of information, enthusiasts have access to a plethora of tools, tutorials, and discussion forums that can assist them in honing their talents and discovering potential that has not yet been exploited. While the hardware features of the Arduino Uno are substantial, the software environment that comes with the Arduino Uno is also rather rich. Among these is the Arduino Integrated Development Environment (IDE), which, because of its user-friendly interface and rich library support, makes it possible for users of varying skill levels to program. With the assistance of the Arduino Uno, a versatile and essential instrument in the field of embedded systems and do-it-yourself electronics, anyone can confidently construct and develop for educational, prototype, and commercial applications. This is because the Arduino Uno is widely used. Creators, educators, and innovators from all over the world prefer this platform due to its low cost, user-friendliness, and the potential to be customized at their own discretion. Because of this, we now live in a culture that places a high value on creativity and innovation, and the rate at which technical improvements have occurred has been unprecedented.
It is widely utilized for the development of interactive electronic prototypes due to the fact that it has a sizable community that facilitates the sharing of projects and resources, as well as an environment that is simple to use for programming. The board can be programmed with the assistance of the integrated development environment (IDE) that is available for Arduino. This IDE is compatible with a simplified version of the C++ programming language.

**Programming in Arduino UNO**

In order to make a connection to the Arduino IDE, the Arduino board must first establish a connection to a computer through the use of USB. It is the Integrated Development Environment (IDE) that is used to write the code for the Arduino before it is transferred to the microcontroller for execution. The C++ code that is included in this package contains methods and functions that have been modified so that they are compatible with the Arduino platform. The Integrated Development Environment (IDE) is the piece of software that is utilized the most frequently when dealing with Arduino programming. In addition to making the process of development simpler for users of varying ability levels, it enables users to easily generate, edit, and upload code.

**(b) MQ-3 Sensor**

An example of a module that is capable of detecting a wide range of gases is the MQ3 alcohol gas sensor. This module can detect alcohol (CH4), benzene, gasoline, hexane, carbon monoxide, and LPG. Through the utilization of a sensitive substance known as SnO2, the device is able to determine whether or not alcohol gas is present. The electrical conductivity of this material reduces after it has been exposed to fresh air. Because it is equipped with a semiconductor alcohol gas sensor, this device is able to detect and monitor the levels of alcohol that are present in the air.

All of the following substances can be identified using the MQ-3 module: benzine, alcohol, liquefied petroleum gas (LPG), hexane, CH4, and carbon monoxide. SnO2, a sensitive substance that exhibits lower conductivity in clean air, is the material that the MQ-3 gas sensor is dependent on. There is a correlation between the conductivity of the sensor and the concentration of the alcohol gas that is being measured. Furthermore, the MQ-3 gas sensor is extremely resistant to interference from fuel, smoke, and vapour, in addition to having a high level of sensitivity to alcohol.
The analogue resistive output that this sensor generates is determined by the concentration of alcohol. The conductivity of the sensor increases in a manner that is directly proportional to the amount of alcohol gas present. In order for the MQ-3 sensor to detect gasses, it must first undergo a chemical reaction. In order to raise the temperature of a metal oxide semiconductor (MOS) sensor, the device makes use of a relatively modest heating component. The MOS sensor goes through a chemical reaction that causes it to change its electrical resistance when it is exposed to the fumes of alcohol that are present in the atmosphere.

**Applications of MQ-3 Sensor**

A wide variety of applications can be found for the MQ-3 Alcohol Sensor, which is a multi-functional device. When alcohol concentration levels reach specified thresholds, it acts in a manner that is analogous to that of a gas level alarm, thereby warning users of the potential dangers that may be present. Because of its little size and low weight, it is ideally suited for use as a portable alcohol detector, which enables screening to be carried out expeditiously and easily in a variety of environments. When the sensor is included into breathalyzers, it is able to offer accurate readings of the blood alcohol concentration (BAC) in breath samples. This information is helpful for both official investigations and the monitoring of an individual's health. Using different sensor modules, the system may be modified to detect alcohol vapor in real time in a variety of environments. This is made possible by the fact that the system is modular. In addition, the MQ-3 sensor allows for the determination of air quality and the detection of ethanol emissions, both of which contribute to environmental monitoring. It is able to determine whether passengers are under the influence of alcohol and discourage them from operating motor vehicles, which results in an increase in the overall safety of automotive passengers. Due to the fact that it is dependable and versatile, the MQ-3 Alcohol Sensor is an essential component in the process of enhancing safety, effectiveness, and welfare in a variety of different areas. For the purpose of measuring different kinds of gases for a variety of purposes, a number of different gas sensors have been developed. Methane, butane, LPG, and smoke are all able to be detected by the MQ-2 sensor. On the other hand, the MQ-3 sensor is primarily focused on detecting alcohol, ethanol, and smoke above the other substances. When it comes to detecting gases, the MQ-5 is specifically designed to identify natural gas and propane, whilst the MQ-4 is utilized for identifying methane and compressed natural gas with its specialized capabilities. In spite of the fact that the MQ-7 is specifically designed for CO detection, the MQ-6 is also capable of detecting LPG and butane. In contrast to the MQ-9 sensor, which is capable of detecting combustible gases in addition to carbon monoxide, the MQ-8 sensor is only capable of detecting hydrogen gas. It is also important to note that the MQ135 sensor is responsible for monitoring the overall air quality, whereas the MQ131 sensor is responsible for testing specific gases such as ozone. Ammonia can be recognized by the MQ137 sensor, whereas hydrogen sulphide gas can be detected by the MQ136 sensor. Both sensors are able to detect gases. Hydroxogen, formaldehyde gas, benzene, toluene, alcohol, and propane are all substances that can be detected by the MQ138 sensor. Additionally, the MQ214 sensor is able to detect natural gas as well as methane, but the MQ216 sensor is specifically designed to detect both natural gas and coal gas without any interference. The MQ303A, MQ306A, MQ307A, and MQ309A sensors are designed to detect flammable gases, alcohol, smoke, LPG, butane, and carbon monoxide. Additionally, they are able to detect carbon monoxide. These sensors have the potential to be useful in a wide variety of applications with respect to the environment, industry, and safety.
Polarizers and the light-modulating properties of liquid crystals are utilized in optical devices; examples of such devices include liquid crystal displays (LCDs). Due to the fact that liquid crystals do not directly emit light, they require a backlight or reflector in order to produce images that are either color or monochrome.

The construction of an alcohol detector can be accomplished by combining an Arduino microcontroller with a MQ-3 alcohol sensor system. One option for displaying the alcohol level in a visible manner is to utilize a 16x2 LCD panel. When it comes to alcohol detection, the MQ-3 sensor is an excellent choice because it has both digital and analog output. When compared to digital output, analog signals have the ability to transmit a greater range of values to a microcontroller. These values can vary from 0 to 1023, which is correlated with the amount of alcohol present in the environment. On the other hand, digital output can only transmit binary values of either 1 or 0.

**Features of 16X2 LCD**

One of its many notable characteristics is that it has an operating voltage range that goes from 4.7V to 5.3V, which ensures that it will function in a consistent and trustworthy manner. The display is composed of two rows, and each row has the capacity to display sixteen characters. Data can be displayed here since there is sufficient space. A low current consumption of 1 milliampere (mA) and the absence of a backlight are two factors that contribute to the device's power efficiency. It is possible to create each character by utilizing a box that is 5 by 8 pixels in size. This allows the letters and numbers to stand out and is simple to read. Because it has two different modes of operation—four-bit and eight-bit—the liquid crystal display (LCD) is compatible with and versatile for a wide variety of applications. The choice between blue and green lights allows one to personalize it in accordance with their preferences and the settings they have chosen. In addition to that, the LCD may display characters that are determined by the user, which means that it is able to display information that is individualized to meet the requirements and preferences of each individual.

**3.6. Observation**

If Alcohol Level is High, the Buzzer will Alarm, LED will glow according to LED Colour and Measure the Level of Alcohol. If Alcohol Level is Low, The Buzzer will not Alarm and LED will not glow.
3.6.1. Observation of Alcohol Detector

The MQ-3 alcohol sensor possesses numerous benefits, rendering it a widely favored option for diverse applications. First and foremost, it is offered at a reasonable price, making it easily obtainable for a wide range of tasks. Additionally, it provides an extended life span, guaranteeing prolonged functionality and dependability. The excellent stability of the device guarantees reliable and precise measurements that remain consistent over an extended period. Moreover, its heightened sensitivity enables quicker reaction times, hence improving its efficacy in promptly detecting alcohol levels. The sensor necessitates an uncomplicated drive circuit and is uncomplicated to utilize, rendering it appropriate for both novices and proficient users alike. Additionally, its interoperability and user-friendly interface with microcontrollers streamline the integration process into various systems. When used in an automobile, employing an alcohol sensor can offer vital safety precautions, enabling protection in situations where individuals are intoxicated. During such circumstances, alternate family members can assume the role of driving, so guaranteeing road safety. Moreover, the sensor can protect the vehicle from unwanted entry, providing an additional level of protection to the car.

3.6.2. Source Code

```cpp
#include <LiquidCrystal.h> //Libraries

LiquidCrystallecd(2, 3, 4, 5, 6, 7); //Arduino pins to lcd

#define sensor_pin A0
#define G_led 8
#define R_led 9
#define buzzer 13
```
float adcValue=0, val=0, mgL=0;

void setup(){ // put your setup code here, to run once
  pinMode(sensor_pin, INPUT);
  pinMode(R_led, OUTPUT); // declare Red LED as output
  pinMode(G_led, OUTPUT); // declare Green LED as output
  pinMode(buzzer, OUTPUT); // declare Buzzer as output
  lcd.begin(16, 2); // Configure lcd numerocolumnas y filas
  lcd.clear();
  lcd.setCursor(0,0);
  lcd.print("Welcome To ");
  lcd.setCursor(0,1);
  lcd.print("Alcohol Detector");
  delay(2000); lcd.clear();
}

void loop() {
  adcValue=0;
  for(int i=0;i<10;i++){
    adcValue+= analogRead(sensor_pin); delay(10); }
  val = (adcValue/10) * (5.0/1024.0); mgL = 0.67 * val;
  lcd.setCursor(0,0);
  lcd.print("BAC:");
  lcd.print(mgL,3);
  lcd.print("mg/L");
  lcd.setCursor(0,1);
  if(mgL>0.8){
    lcd.print("Drunk");
    digitalWrite(buzzer, HIGH); digitalWrite(G_led, LOW); // Turn LED off.
    digitalWrite(R_led, HIGH); // Turn LED on.
    delay(300);
  }
  else {
    lcd.print("Normal");
  }
digitalWrite(G_led, HIGH); // Turn LED on.

digitalWrite(R_led, LOW);  // Turn LED off.
}
digitalWrite(buzzer, LOW);
delay(100);
}

To begin, use the programming cable to connect the Uno board to the computer. Ensure that the USB side of the cable is firmly connected into the computer. The next step is to launch the Arduino Integrated Development Environment (IDE) and proceed to insert the code that has been provided. It is important to make sure that the correct board is selected before beginning the upload process. To do this, go to the "Tools" menu and pick "Arduino Uno." In the same manner, using the "Tools" menu, select the appropriate port in order to confirm the appropriate port number. When you have finished verifying these criteria, you should next proceed to click the upload button. Immediately following the completion of the upload, the USB cord should be disconnected from the Uno board. The Arduino Uno is currently capable of being powered by an external battery. This feature is available to it. It is important to note that there is no requirement for an additional resistor when utilizing a 3.7V battery. Regarding batteries that have a higher voltage, however, it is possible that appropriate resistors will be required depending on the voltage levels. This strategy has the ability to reduce the number of accidents that are brought on by the consumption of alcohol in the future. This system improves the safety and well-being of individuals within the population. This will allow for substantial breakthroughs to be made in the automotive industry with the goal of reducing the number of accidents that are caused by alcohol. The investigation of alcohol detection with the use of Arduino is a fascinating field. In the development of an alcohol detection system, this technology demonstrates a great deal of potential as a prospective application. This technology has the potential to reduce the number of accidents that are caused by drivers who are under the influence of alcohol or drugs, hence reducing the number of incidents that would otherwise occur. It is currently in the beginning stages of development that alcohol detection systems that make use of Arduino technology are being developed. This leaves a significant amount of potential for additional research and inquiry in this area. The enhancement of the system's precision, the reduction of the system's size, and the development of innovative applications for the technology are all potential areas within which research might be conducted.

4. Results and Discussion

Within the guide, you will find a breadboard, an Arduino board, a red LED, a MQ-3 alcohol sensor, and a complete inventory of all the components that are required for the project. Additionally, the tutorial provides a detailed, step-by-step guidance on how to construct the circuit, in addition to providing a schematic illustration of the MQ-3 sensor. From the MQ3 sensor's features to its pinout configuration and the instructions on how to connect it to an Arduino, this article covers every single component of the MQ3 sensor. Through the use of a MQ-2 sensor module, the author of this article explains how to construct a portable, battery-operated gadget that is capable of detecting alcohol.
alcohol and displaying the results on an LCD screen. In the instructions, the components that are required for the project are specified as follows: an integrated circuit with the model number LM358; a 16x2 liquid crystal display; a buzzer; and a MQ3 sensor.

4.1. Designed Model

Alcohol detectors that are based on Arduino are a straightforward device that can determine whether or not alcohol is present in the air that is inhaled. The research makes use of a MQ-3 alcohol sensor in order to determine whether or not there are any traces of alcohol present. An LCD or LED screen is used to display the results of the processing of the data that is received from the sensor by an Arduino board, which then displays the results. It is possible for the MQ-3 sensor to accurately assess the amount of alcohol that is present in the surrounding environment since it possesses a high degree of sensitivity to alcohol. Signals of both digital and analogue types could be produced by the sensor. The distinction between digital and analog signals is straightforward: digital signals can only send one of two values—1 or 0—to a microcontroller, whereas analog signals can convey a wide range of values—from 0 to 1023—that measure the amount of alcohol that is present in the air. Due to the fact that it is simple to construct, this project is ideal for displaying straightforward tiny projects or because it may be utilized in smaller devices.

5. Conclusion

In conclusion, we have gained the knowledge necessary to know how to connect a MQ3 alcohol sensor to an Arduino by utilizing the digital and analog output pins of the sensor. In addition to this, we discovered that the alcohol sensor module can be calibrated by using the AOUT and DOUT pins. There is a significant amount of interest among students and hobbyists in the construction of alcohol detectors utilizing the Arduino platform. Additionally, an Arduino board and a MQ-3 alcohol sensor are utilized in this project in order to ascertain whether or not there is alcohol present in the atmosphere. The sensor detects the vapor or smell of alcohol, and it then transmits a signal to the Arduino board in order to receive the information. The signal is then processed by the circuit, and if it determines that alcohol is present, it activates either a warning light or an LED. Authors searched over the entire internet for a definitive response to this assignment, but authors were unable to locate one. On the other hand, authors were able to locate a Techatronic guide that provides a comprehensive explanation of everything that is required to construct an alcohol detector using an Arduino and a MQ3 sensor. Through the course of the presentation, you will be presented with in-depth explanations of the components, the circuit diagram, and the
To construct your very own alcohol detector using Arduino, all you need to do is follow the methods outlined in the article.

The technologies that are utilized in the system that is being suggested are more than capable of ensuring that the intoxicated driver will make a full recovery. In each and every endeavor, there is the potential for improvement. There are several adjustments that need to be performed in order to make this process more efficient. There is a possibility that in the future, this system will be improved by being made smaller. The alcohol system is made more user-friendly through the process of miniaturization, which in turn enhances the likelihood that drivers may accept intoxicating substances. It is of the utmost importance to position the alcohol sensor in such a way that it can be readily and correctly measured the amount of alcohol consumed by the driver, regardless of whether or not the driver is there to provide help.
